A controllable work speed can be attained in such a system by means of the control valve. In a very simple embodiment, such a valve can be constructed as a two-position valve, which is actuated by hand and may have a very small construction. In this case, however, such a valve can be of only marginal use, so that a much more sophisticated valve is required. This valve must not only serve for producing the stepless work speed, but also have the features that it may be operated electrically, i.e. in a contactless manner, and, furthermore, that it will not start to work before the power supply is connected, so that a reliable actuation of the motor is guaranteed. Such a system is known, for example, from DE 33 26 963 A1. In this system, a triac with a variable switching time is connected in series with the triac-controlled motor. This series circuit arrangement is ca3bfb1094
